Brainstorming & Ideation Phase

Project Title	Implement Client Scrip & UI Policy(Incident)
Team Name / ID	Team 3
Team Members	s.ezhilmanibala,R.ilakkiya,Saravanan,durai Balaji,lathika
Date	28/09/2026

1. Problem Statement

- Incident records often contain incomplete, inconsistent or incorrect data because the process relies on user awareness and manual checks. This hurts triage, routing, SLA compliance and reporting accuracy.
- **Target users:** service desk agents who log incidents, resolver groups who receive them, and service managers who depend on the data. Clean data at entry saves time for all of them.

2. Idea Generation

Idea	Description	Pros	Cons
Idea 1	Make fields mandatory through dictionary settings	Simple, one-time change	Applies to every incident; too rigid
Idea 2	UI Policy + Client Scripts on the Incident form	Conditional, reversible, instant feedback to the user	Client-side only; can be bypassed by imports / APIs
Idea 3	Server-side Business Rule / Flow validation	Enforced for all sources including APIs	Feedback only after submit; needs server-side coding

3. Idea Prioritization

- **Criteria used:** feasibility, cost, time, user impact, technical skill of team.
- **Selected idea:** Idea 2 (UI Policy + Client Scripts) - **Reason:** it is easy to build with basic ServiceNow skills, needs no extra cost, gives users immediate feedback, and can be completed in the short project time.

4. Proposed Solution

Implement a **High Impact Control** UI Policy together with three Client Scripts on the Incident table so that High-impact incidents are always created with complete, valid data. The unique value is that rules are applied conditionally and reverse automatically, without any server-side code.

Key features:

- Assignment group becomes mandatory when Impact = High.
- Urgency is auto-set to High and made read-only (onChange script + UI Policy Action).
- Save is blocked when Assigned To is empty for High-impact incidents (onSubmit).
- State cannot be changed from list view (onCellEdit); Reverse if false restores fields when Impact changes.

5. Team Roles & Contributions

Member	Role	Contribution in this phase
[Name]	Team Lead	Defined the problem statement and coordinated brainstorming sessions
[Name]	Developer	Suggested the UI Policy and Client Script approach; compared ideas
[Name]	Developer / Tester	Researched existing ServiceNow validation options and their limits
[Name]	Documentation	Recorded ideas, prioritization and prepared this document

6. Brainstorming Techniques Used

- Mind mapping, group discussion, SWOT analysis, and reference to existing similar systems.
- **Key points raised:** members highlighted the need for conditional rules (only for High impact), instant user feedback, easy reversal when Impact changes, and a small scope that can be tested fully. The team compared server-side and client-side options before choosing.

7. Existing Systems & Gap Analysis

- **Dictionary-level mandatory fields:** apply to all records regardless of impact, so they are too rigid.

- **Manual review by service desk leads:** slow, inconsistent and does not scale.
- **Server-side Business Rules / Data Policies:** strong enforcement but give feedback only after submit.
- **Improvement:** this project gives conditional, real-time and reversible validation on the form itself, with lightweight configuration.

8. Expected Outcome & Benefits

- **Benefits:** higher data quality, faster triage and routing, better SLA compliance, cleaner reports and a smoother experience for agents.
- **Success criteria:** all 7 test cases pass, High-impact incidents cannot be saved without Assigned To, and fields revert correctly when Impact changes.

9. Notes / Space for Diagrams

Mind map of the selected idea:
